Problem 1: The relativistic hydrogen atom (Written, 6+1 points)

Learning objective

From your quantum mechanics course, you know how to solve the non-relativistic Schrödinger equation for the hydrogen atom. Here we describe the electron of the hydrogen atom by the relativistic Dirac equation instead. That is, we interpret the bispinor field $\psi(x)$ as a single-particle wavefunction (not an operator!) and the Dirac equation as the relativistic analogue of the non-relativistic Schrödinger equation. For the hydrogen atom, we will see that corrections that had to be put in by hand in the non-relativistic description now emerge naturally (notably, the fine structure).

To describe the electron in the hydrogen atom by the Dirac equation, we incorporate the coupling to an external (classical) electromagnetic field—described by the gauge field $A_\mu$—via minimal coupling

$$\partial_\mu \mapsto D_\mu = \partial_\mu + ieA_\mu,$$

where $e < 0$ is the electric charge of the electron. The Dirac equation now reads

$$\left(\frac{i}{D} - m\right)\psi = \left(\frac{i}{\partial} - eA - m\right)\psi = 0,$$

where $A = \gamma^\mu A_\mu$ as usual.

The elementary charge $|e|$ is dimensionless in natural units ($\varepsilon_0 = c = \hbar = 1$); it is the coupling constant of quantum electrodynamics and describes the strength of the coupling between charged particles and the electromagnetic field. It is related to the fine-structure constant by $\alpha = \frac{e^2}{4\pi} \approx \frac{1}{137}$.

a) Show that Eq. (2) is invariant under the gauge transformation

$$A_\mu(x) \mapsto A_\mu(x) - \partial_\mu \lambda(x) \quad \text{(3a)}$$
$$\psi(x) \mapsto e^{ie\lambda(x)}\psi(x) \quad \text{(3b)}$$

for arbitrary $\lambda(x)$.

b) Multiply the Dirac equation (2) by $(i\partial - eA + m)$ and bring your result into the form

$$\left[(i\partial - eA)^2 - eS^{\mu\nu}F_{\mu\nu} - m^2\right]\psi = 0,$$

with the generators of the Lorentz algebra

$$S^{\mu\nu} = \frac{i}{4} [\gamma^\mu, \gamma^\nu] \quad \text{(5)}$$

and the electric field tensor $F_{\mu\nu} = \partial_\mu A_\nu - \partial_\nu A_\mu$.

Using the gauge invariance of the Dirac equation, we choose for the four-potential

$$A_0 = -\frac{Ze}{4\pi r} \quad \text{and} \quad A_i = 0 \quad \text{(6)}$$
to describe the Coulomb potential of a nucleus with $Z$ protons.

Use this to show that
\[
e S_{\mu\nu} F_{\mu\nu} = i \frac{Z \alpha}{r^2} \begin{pmatrix} \sigma \cdot \hat{r} & 0 \\ 0 & -\sigma \cdot \hat{r} \end{pmatrix}
\]

with $\hat{r} = r/r$.

**Note:** Use the Weyl representation of the gamma matrices from Peskin & Schroeder.

Thus (4) is block-diagonal and we can make the ansatz $\psi(x) = e^{-iE_t} (\phi_+(\mathbf{r}), \phi_-(\mathbf{r}))^T$ with two-component spinors $\phi_\pm$ to derive the spectrum $E$.

Show that Eq. (4) reduces to
\[
\left[ -\left( \frac{\partial^2}{r} + \frac{2}{r} \frac{\partial}{r} \right) + \frac{L^2}{r^2} - \frac{Z^2 \alpha^2 \pm iZ\alpha \cdot \hat{r}}{r} - \left( E^2 - m^2 \right) \right] \phi_\pm = 0,
\]

where $L$ is the (orbital) angular momentum operator.

**Hint:** Recall that
\[
\Delta = -\partial_i \partial^i = \partial^2 + \frac{2}{r} \frac{\partial}{r} - \frac{L^2}{r^2}
\]
in spherical coordinates.

c) To solve the differential equation (8), we introduce the total angular momentum operator $J = L + \frac{1}{2} \sigma$.

Explain why $J$ commutes with the differential operator in (8) and with $L^2$.

d) Consider now the subspace where $J^2 = j(j+1)$, $J_z = m_j$ (for $j = \frac{1}{2}, \frac{3}{2}, \ldots$ and $-j \leq m_j \leq j$) and $L^2 = l(l+1)$. For given $j$ and $m_j$, only two values $l_\pm = j \pm \frac{1}{2}$ for $l$ are possible. Thus an arbitrary state $|j, m_j, l, s \rangle$ can be decomposed into the orthogonal states $|l_\pm \rangle \equiv |j, m_j, l, s = \frac{1}{2} \rangle$.

Show that in the two-dimensional subspace spanned by $|l_\pm \rangle$, we can write
\[
L^2 - Z^2 \alpha^2 \pm iZ\alpha \cdot \hat{r} = \left( j + \frac{1}{2} \right)^2 - Z^2 \alpha^2 = \begin{pmatrix} j + \frac{1}{2} \pm iZ\alpha \\ \pm iZ\alpha \end{pmatrix}
\]

**Hint:** Use the matrix elements $\langle l_\pm | \sigma \cdot \hat{r} | l_\pm \rangle = 0$ and $\langle l_\pm | \sigma \cdot \hat{r} | l_\mp \rangle = 1$.

Write the two eigenvalues of (10) in the form $\lambda_k (\lambda_k + 1)$ and show that
\[
\lambda_1 = \left( j + \frac{1}{2} \right) - \delta_j \quad \text{and} \quad \lambda_2 = \left( j - \frac{1}{2} \right) - \delta_j
\]

with
\[
\delta_j = j + \frac{1}{2} - \sqrt{\left( j + \frac{1}{2} \right)^2 - Z^2 \alpha^2}.
\]

e) **Optional (+1 point):** Prove the previous hint.

That is, show that $\langle l_\pm | \sigma \cdot \hat{r} | l_\pm \rangle = 0$ and $\langle l_\pm | \sigma \cdot \hat{r} | l_\mp \rangle = 1$. 

Page 2 of 4
f) In the corresponding eigenbasis, Eq. (8) takes the form

\[
- \left( \frac{\partial^2}{r^2} + 2 \frac{\partial}{r} \right) + \frac{\lambda_k (\lambda_k + 1)}{r^2} - \frac{2Z \alpha E}{r} - \left( E^2 - m^2 \right) \varphi = 0
\]

where \( \varphi = \varphi(r) \) describes only the radial part of \( \phi_\pm(r) \).

**Note:** \( \varphi(r) \) is a scalar function without angular dependence of its argument whereas \( \phi_\pm(r) \) is a (two-component) spinor field with angular dependence of its argument.

Make the substitutions

\[
\tilde{\alpha} = \frac{\alpha E}{m} \quad \text{and} \quad \tilde{E} = \frac{E^2 - m^2}{2m}
\]

and show that Eq. (13) takes the form of the Hamiltonian for the non-relativistic hydrogen atom:

\[
- \left( \frac{\partial^2}{r^2} + 2 \frac{\partial}{r} \right) + \frac{\lambda_k (\lambda_k + 1)}{r^2} - \frac{2Z m \tilde{\alpha}}{r} - 2m \tilde{E} \varphi = 0.
\]

Use your knowledge from your quantum mechanics course to derive the eigenenergies \( E = E_{nj} \) and show that the spectrum is given by

\[
E_{nj} = \frac{m}{\sqrt{1 + \frac{Z^2 \alpha^2}{(n - \delta_j)^2}}},
\]

where \( n = 1, 2, \ldots \) and \( j = \frac{1}{2}, \frac{3}{2}, \ldots, n - \frac{1}{2} \).

**Hint:** To determine the spectrum \( \tilde{E} \) in Eq. (15), use the substitution \( \varphi(r) = \frac{u(\rho)}{r} \) and that the spectrum \( \epsilon^2 \) of the differential equation

\[
\left[ \frac{\partial^2}{\rho^2} - \frac{l(l + 1)}{\rho^2} + \frac{2}{\rho} - \epsilon^2 \right] u(\rho) = 0
\]

is given by \( \epsilon^2 = (l + 1 + \nu)^2 \) with \( \nu = 0, 1, 2, \ldots \).

What is the difference between \( l \) and \( \lambda_k \)?

**g)** Expand the energy \( E_{nj} \) up to fourth order in \( \alpha \).

What are the differences to the non-relativistic spectrum?

How is the \( j \)-dependence of \( E_{nj} \) called?
Problem 2: Parity transformation of Dirac spinors (Written, 4 points)

Learning objective

The Dirac equation is Lorentz-covariant under proper, orthochronous Lorentz transformations (which continuously connect to the identity). Spatial inversion (parity) is a discrete generator of the complete Lorentz group that allows for “improper” Lorentz transformations. Here we study the representation of this symmetry on the spinor fields of the Dirac theory. We will find that the Dirac Lagrangian is invariant under parity transformations.

In addition to the continuous (proper and orthochronous) Lorentz transformations (that is, rotations and boosts), there are three discrete symmetries acting on the spinor fields: Parity (P), time reversal (T) and charge conjugation (C).

Here we focus on the transformation of parity P which inverts all spatial coordinates

\[ P : \mathbb{R}^{1,3} \rightarrow \mathbb{R}^{1,3}, \quad (t, \mathbf{x}) \mapsto (t, -\mathbf{x}) \]  

and thereby the three-momentum of a particle without flipping its spin: \( p \mapsto -p \) and \( s \mapsto s \) [motivate this from Eq. (18)].

Mathematically, this means that \( P \) should be represented by a unitary operator acting on the Hilbert space of the Dirac theory. For example, \( P \) transforms single-particle states \( a^s_p |0\rangle \) into \( a^s_p |0\rangle \).

Thus we define on the mode algebra

\[ Pa^s_p P = \eta_a a^s_{-p}, \quad Pb^s_p P = \eta_b b^s_{-p}, \]  

where \( \eta_a \) and \( \eta_b \) are possible phases.

a) We make two observations:

- Two applications of the parity operator should “do nothing”, i.e., arbitrary observables commute with \( P^2 \).
- Physical observables are built from an even number of fermion operators (this is known as a superselection rule).

What are the allowed values for \( \eta_a \) and \( \eta_b \)?

b) We proceed with the quantized Dirac fields (here \( x \) is a four-vector \( x = (t, \mathbf{x}) \)):

\[
\psi(x) = \int \frac{d^3 p}{(2\pi)^3} \frac{1}{\sqrt{2E_p}} \sum_s \left( a^s_p u^s(p)e^{-ipx} + b^s_p v^s(p)e^{ipx} \right), \tag{20a}
\]

\[
\bar{\psi}(x) = \int \frac{d^3 p}{(2\pi)^3} \frac{1}{\sqrt{2E_p}} \sum_s \left( b^s_p \bar{u}^s(p)e^{-ipx} + a^s_p \bar{v}^s(p)e^{ipx} \right). \tag{20b}
\]

Show that the fields transform as follows:

\[ P\psi(t, \mathbf{x})P = \eta_a \gamma^0 \psi(t, -\mathbf{x}), \quad \text{and} \quad P\bar{\psi}(t, \mathbf{x})P = \eta_a^* \bar{\psi}(t, -\mathbf{x}) \gamma^0. \]  

(21)

c) Using the transformation of the fields, evaluate the fermion bilinears

\[ P\bar{\psi}\psi P, \quad P\bar{\psi}\gamma^\mu\psi P, \quad P\bar{\psi}[\gamma^\mu, \gamma^\nu]\psi P, \quad P\bar{\psi}\gamma^{\mu+\nu}\psi P, \quad \text{and} \quad P\bar{\psi}\gamma^5\psi P. \]  

(22)

d) Finally, show that the Dirac Lagrangian \( \mathcal{L}_D = \bar{\psi} \left( i\gamma^\mu \partial_\mu - m \right) \psi \) is invariant under parity transformations.
